

## TRAINING DEVICE FOR GOLF SWING AND SIMILAR MOTIONS

### TECHNICAL FIELD

The present invention relates to a training device for a golf swing and similar motions. More particularly, the present invention relates to a training device that guides and coordinates a user's body position and lateral, vertical, and rotational arm and body movement that executes a golf swing or performs  
5 other similar motions, and that further can record a golf swing motion and can force the user to repeat the motion or perform another desired similar motion.

### BACKGROUND ART

The present invention has special application to the teaching of a golf  
10 swing, and it will be described with particularity with regard to this use. When a golfer properly executes a golf swing, the relatively planar face of a golf club head moving at a relatively high velocity collides with a golf ball that is at rest on or near the ground. The force of the collision causes the golf ball to compress slightly against the face of the club head, which may also undergo  
15 some temporary deformation. Because the mass of the golf ball is significantly less than that of the moving club head, the collision also causes the golf ball to become accelerated in the direction of the force being applied to it by the club head. The face of the club head is usually lofted a predetermined number of degrees from vertical and scored with horizontal  
20 grooves. The horizontal grooves in the face of the club head engage the relatively soft cover of the golf ball during compression and prevent the ball from sliding up the face. As the golf ball decompresses and begins to spring off of the face of the club head, the horizontal grooves coupled with the loft angle of the club frictionally impart a backward spin and a rising trajectory to  
25 the golf ball. The spin axis of a properly struck golf ball is substantially horizontal and perpendicular to a target line, which is an imaginary line

-2-

extending horizontally in the direction of an intended target from the point at which the golfer struck the golf ball with the golf club. After springing off of the face of the club head, a properly struck golf ball, which is usually dimpled to reduce drag and increase lift, travels in a desired direction for a desired distance and comes to rest again on the ground at the intended target, assuming of course that the flight of the ball is not affected by other forces, such as wind.

It will be appreciated that the golf ball is in contact with the face of the club head for only a brief period of time during the golf swing. However, if the golf ball is to travel on a straight path to the intended target, meaning that the golf ball generally travels in a vertical plane that contains the target line, it is imperative that throughout the brief period of time the golf ball is in contact with the golf club the golfer maintains the club head such that the horizontal grooves in the club face are substantially perpendicular (i.e., square) to the target line. To hit a straight shot, it is also imperative that the golfer maintain the movement of the golf club such that the club face moves substantially along the target line while it is in contact with the ball. And, for most golf shots, it is also imperative that the golfer cause the club head to be moving at a relatively high rate of speed at the time of the collision with the ball in order to impart a sufficient force to the golf ball to cause it to travel to the intended target.

If the golf swing is not executed as described, the golf ball will not travel on a generally straight path to the intended target. For example, if the horizontal grooves in the club face are not substantially perpendicular to the target line when the head of the golf club strikes the golf ball, the spin axis of the golf ball will not be substantially horizontal and perpendicular to the target line, and the golf ball will tend to curve in flight to the right or to the left of the direction of the force applied by the club. For a right-handed golfer, a trajectory deviation to the right of the target line caused by an improper spin imparted to the golf ball is referred to as a slice, and a trajectory deviation to the left caused by an improper spin imparted to the golf ball is referred to as a hook. In addition, if the movement of the club head while it is in contact with

-3-

the golf ball is in a direction other than substantially along the target line, the force transferred to the golf ball will cause it to become accelerated to the right or left of the target line, which for a right-handed golfer is called a push or pull, respectively. These terms are reversed for a left-handed golfer. Other factors, such as the steepness or shallowness of the swing arc of the golf club, the velocity and acceleration of the golf club head at the moment of impact, the point on the face of the golf club which makes contact with the golf ball, and other factors can also have a significant affect on whether the golf ball comes to rest near its intended target.

Significant practice is required in order for a golfer to learn how to execute a golf swing that will result in a golf ball consistently traveling to an intended target. Unfortunately, if during such practice the golfer learns poor swing mechanics or other bad habits resulting in swing flaws, such flaws can become grooved in the golfer's swing. In other words, the golfer's muscles become accustomed to executing a golf swing having one or more flaws or faults. A golfer who has grooved a swing with a flaw or fault has a very difficult time correcting the golf swing, primarily because the golfer does not know what a proper swing is supposed to feel like. Accordingly, rather than correcting the swing flaw, the golfer will more likely make a compensation in some other portion of the swing to adjust for the improper flight characteristics of the golf ball caused by the swing flaw. A classic example of this situation is a right-handed golfer with a swing flaw which produces a pronounced slice compensating for the slice by aiming far to the left of the intended target. Making compensations such as this may allow the golfer to hit the golf ball in the general direction of the intended target, but such compensations result in a loss of distance, decreased accuracy, and inconsistency. Furthermore, making such compensations tends to compound the number of swing flaws in the golfer's swing, making it even worse and more difficult to correct. Accordingly, it is better to learn and groove proper golf swing having no flaws or faults.

A proper golf swing begins from an address position and includes a back swing, a down swing, and a follow through. In the address position, the

-4-

golfer stands a distance away from and facing the golf ball. The golfer's feet are placed generally astride an imaginary horizontal line that passes through the golf ball perpendicular to the target line. The golfer takes a comfortable grip on the grip end of the golf club and places the club head to the side of the golf ball opposite the target.

The first part of the golf swing is called the back swing. During the back swing, the golfer takes the club head away from the golf ball while rotating (i.e., turning) his or her hips and upper torso away from the intended target. Ideally, the golfer's shoulders should rotate up to about 90°, and the golfer's hips should rotate up to about 45° from the address position during the back swing. At the same time, the golfer raises the golf club in his or her hands by tilting the wrists. Once the golfer has completed the back swing, the golfer then executes the second part of the golf swing called the down swing. The point at which the golfer transitions from the back swing to the down swing is called the top of the back swing. During the down swing, the golfer turns back toward the golf ball and brings the wrists down to move the club head to the original position. The golfer strikes the golf ball with the face of the club head at the bottom of the down swing. In the brief period of time that the golf ball is on the club face, the down swing transitions into the third part of the golf swing called the follow through. During the follow through, the golfer completes a turn in the direction of the intended target and again moves the wrists to lift the club. Ideally, the golfer's shoulders should rotate up to about 180° and the golfer's hips should rotate up to about 90° from the position they were in at the top of the back swing.

Videotape recordings and stop-action photographs taken of professional golfers show that, in addition to the rotational body movement previously described, a proper golf swing also involves lateral and vertical movement. From the address position, the upper torso of most professional golfers moves laterally away from the intended target a distance in a direction generally parallel to the target line as the golfer turns or rotates his or her hips and shoulders away from the target during the back swing. This lateral movement coupled with the simultaneous rotation of the golfer's hips and

-5-

shoulders causes the golfer to also simultaneously move a distance in a generally downward direction (i.e., toward the horizontal plane that includes the target line) during the back swing. During the down swing, the golfer simultaneously counter-rotates by turning his or her hips and shoulders back  
5 toward the golf ball while his or her upper torso moves laterally generally parallel to the target line in the direction of the intended target. The uncoiling of the golfer's body during the down swing results in a simultaneous upward or vertical movement relative to the horizontal plane containing the target line. During the follow through portion of the golf swing, the golfer's hips and  
10 shoulders complete a body turn toward the target and the golfer continues to move laterally generally parallel to the target line toward the target. As the golfer completes the follow through the golfer simultaneously continues to rise or move in a generally vertical direction relative to the horizontal plane.

The prior art is replete with training devices that are intended to guide a  
15 user through the proper mechanics of a golf swing. Unfortunately, these prior art devices universally fail to account for the lateral and vertical movements of the user's body during a properly executed golf swing. In fact, most prior art mechanical training devices force the user to execute a golf swing by rotating about a single fixed axis thereby training the user to attempt to execute the  
20 golf swing without making any lateral and/or vertical movements. Clearly, such prior art mechanical training devices do not take into account the dynamic movement of the human body during a properly executed golf swing. A mechanical device is needed that can guide and coordinate a user's body position and lateral, vertical, and rotational movement when executing a golf  
25 swing so that golfers can learn and practice how to execute a proper golf swing.

In addition, there is no existing device which can teach the golfer to coordinate the wrist movements which involving lifting and lowering the club head with the shoulder movement of twisting to perform the back swing and  
30 the follow through. The speed of these movements and the coordination of the wrist and shoulder movements vary greatly from golfer to golfer. Many golfers who have what is considered to be optimal swings perform these

-6-

movements in different order and with different speeds. The proper swing for any particular golfer is going to vary and a golfer may wish to adopt one of the swings of a professional or amateur golfer with which he or she is familiar, or the golfer may wish to develop his or her own stroke. However, heretofore, the capturing of these movements and the ability of forcing the golfer to perform these movements has been extremely limited.

Some of these disadvantages have been overcome by the training device disclosed in U.S. Patent No. 6,371,863, issued to the present inventor. This device provides guiding and coordinating a user's body position and lateral, vertical, and rotational movement when executing a golf swing relative to the target line. However, the motion provided by the device is generally the same for any golfer, and there is nothing to force the golfer to conform to more desirable swing mechanics. Furthermore, there is no coordination between the movement of the upper torso in swiveling around and the movement of the wrists and arms to lift and lower the golf club during the swing.

The device of U.S. Patent No. 6,371,863 is also limited in its applicability to teaching a golf swing. It is not readily adaptable for other uses, such as teaching other similar types of motion, or for use in physical therapy or kinesiotherapy where other types of shoulder and arm motion can be repetitively taught to the user.

## SUMMARY OF THE INVENTION

The present invention provides an improved training device for various uses, most importantly for training a user how to execute a proper golf swing. The training device according to the present invention guides and coordinates the user's body position and lateral, vertical, and rotational movement when executing a golf swing relative to a target line extending horizontally in the direction of an intended target from a predetermined point at which the user would strike a golf ball with a golf club. At the same time, the device coordinates the movement of the golfer's wrists and arms in raising and

-7-

lowering the golf club head with the swinging movement of the shoulders according to the golfers own unique specification.

The training device of the present invention utilizes servo motors and programmable logic, to guide the user through a predetermined course of motion, in which the upper torso is moved relative to the lower torso, and in which the arms are moved relative to the upper torso. This predetermined course of motion can be programmed to guide the user through a proscribed golf swing motion, in which the user executes a golf swing in a manner different from a swing motion previously employed by the user, or in which the user executes a desired golf swing motion achieved through special lessons. This motion can then be repeated exactly as many times as desired, until the user has achieved a "feel" for the swing, or has fallen into a "groove."

To restrain the user within the training device, the training device according to the present invention includes a yoke, a rotatable member, and a guide assembly. The yoke engages the upper torso of the user and includes an attachment point that is preferably positioned above and intermediate the user's shoulders. The rotatable member is connected to the yoke at the attachment point. The rotatable member has an axis of rotation that lies within a first plane that is generally parallel to the target line of the golf swing. The guide assembly maintains the orientation of the rotatable member as it simultaneously rotates and moves laterally and vertically while the user executes a golf swing. Preferably, the guide assembly maintains the orientation of the rotatable member such that a first angle between the first plane and a horizontal plane that contains the target line, and a second angle between the axis of rotation of the rotatable member and a line of intersection between the first plane and the horizontal plane, both remain constant while the rotatable member simultaneously rotates and moves laterally generally parallel to the target line away from the target and toward the horizontal plane as the user executes a back swing and counter-rotates and moves laterally generally parallel to the target line toward the target and away from the horizontal plane as the user executes a down swing and follow through. In a preferred embodiment, the training device further includes an extensible rod

-8-

that is pivotally connected on one end to the yoke proximal to the user's sternum and is connected on the other end by a hinge to a holder which supports the grip end of a golf club.

A pair of actuators, preferably comprising servo motors, are attached to  
5 this mechanism to monitor and/or drive the rotational shoulder movement of  
the user and the wrist movement which can tilt the golf club shaft. The  
actuators are connected to a control unit, which may be a PC, which receives  
data from the actuators and can use the actuators to drive the mechanism  
through a desired set of movements, such as that of a golf swing. The device  
10 can be set in a learn mode in which the actuators monitor the motion of the  
torso and shoulders and the motion of the wrists and arms in lifting and  
lowering the club head during the golf swing and display this information to  
the user, so that the user and/or a teacher can evaluate the swing. The  
device can also be set in a teaching mode in which the actuators apply a  
15 suitable resistance force to the mechanism to guide the user in the desired  
movement, such as to execute a preprogrammed golf swing. The teaching  
can be enhanced by visual displays on the control unit showing a time plot of  
the measured parameters of the swing and with indicating lights and/or  
sounds showing visually and/or audibly whether the user is conforming to the  
20 desired movement parameters during the swing.

To use the training device according to the present invention to learn  
and/or practice the rotational, lateral, and vertical movements involved in  
executing a proper golf swing or other similar motion, a user first positions his  
or her upper torso in the yoke. In a preferred embodiment, the yoke includes  
25 a front portion disposed generally adjacent to the user's chest, a back portion  
disposed generally adjacent the user's back, and a connecting portion  
connecting the front portion and the back portion and extending to an  
attachment point located above and intermediate the user's shoulders. With  
his or her upper torso positioned in the yoke, the user takes a comfortable  
30 stance a distance away from and facing a golf ball that has been placed on a  
predetermined point on a target line. The user's feet should preferably be  
placed generally astride an imaginary horizontal line perpendicular to the

-9-

target line that passes through the predetermined point on which the golf ball has or would be placed. The user then preferably takes a comfortable grip on the grip end of a golf club that is supported or cradled in the club holder pivotally connected to the end of the extensible rod. The user then assumes  
5 an address position with the head of the golf club placed on the side of the predetermined point opposite the target and subsequently executes a golf swing that includes a back swing, a down swing, and a follow through. The training device according to the present invention guides and coordinates the user's body position and lateral, vertical, and rotational movement during the  
10 golf swing by limiting and controlling the position and movement of the user's upper torso which is engaged in and restrained by the yoke. At the same time the actuators monitor the actions of the user and these actions are recorded by the control unit.

The optional extensible rod and club holder assembly forces the user's  
15 hands and arms to be in the proper position relative to the user's body throughout the golf swing, which results in the golf club being maintained in the proper position (i.e., generally perpendicular) relative to the user's spine and in the proper swing plane during the back swing. At the top of the back swing, the hinge connecting the lower portion of the extensible rod to the club  
20 holder allows the user to properly cock his or her wrists in the appropriate plane. As the user begins the down swing rotation and lowering of the arms, the extensible rod and club holder assembly forces the user to keep the golf club and the arms moving downwardly while the upper torso is rotating which creates the proper swing plane at all times. At the point in the swing at which  
25 the user would impact the golf ball with the head of the golf club, the extensible rod and club holder assembly keeps the user's arms and the golf club in the proper relationship with the horizontal grooves in the face of the club being maintained substantially perpendicular or square to the target line.

It will be appreciated that a user can use the training device according  
30 to the present invention without using the optional extensible rod and club holder assembly. Furthermore, it will be appreciated that a golfer can use the device without gripping a golf club. The golfer can obtain substantial benefits

-10-

simply by repeatedly executing the body movements of a proper golf swing relative to a target line with or without gripping a golf club or hitting a golf ball. Whether using a golf club or not, the training device according to the present invention permits a golfer to exercise the muscles involved in executing a proper golf swing, which helps the user learn and groove the body positions and rotational, lateral and vertical movements of a proper golf swing.

The training device according to the present invention is particularly useful for providing the user with the look, sound, and feel (i.e., kinesthesia) of a properly executed golf swing. As the user executes a golf swing, the yoke guides and coordinates the user's body position and rotational, lateral, and vertical movement. The yoke provides resistance to the user's upper torso if the user attempts to move or rotate in an improper manner while executing the golf swing. The device can be programmed to provide a force to create movement, or to provide resistance against which the user must use force. The ability to require the user to exert force against the action of the device allows the device to be used to assist muscle building and/or endurance as well as the development of motor skills.

Preferably, a user uses the training device according to the present invention while receiving golf instruction from a trained golf teaching professional who can help the user identify and correct swing flaws. After executing repeated golf swings with the training device using his or her own playing clubs, the user's muscles will become accustomed to the feel of a properly executed golf swing, and the user will also know what a properly executed golf swing should look and sound like. Through repeated use of the training device according to the present invention, the user will groove a golf swing which has no flaws or faults. Unlike many of the prior art golf training devices, the training device according to the present invention allows the user to strike golf balls using the user's actual playing clubs during practice which gives the user the ability to feel, see, and hear how a properly struck golf ball reacts.

While the training device of the present invention has special applicability to teaching golf swings, the device may also be used to

-11-

repetitively practice other types of similar motions, and may be particularly useful in physical therapy or kinesitherapy. It has been found that many of the motions used in executing a proper golf swing are also useful in doing other common tasks such as walking, in that the rotational motion of the body in a golf swing combined with the vertical motion of the hands and arms is similar to the motion needed for walking. Thus a person who has experienced a loss of motor skills can be rehabilitated by performing these motions using the training device of the present invention.

These and other advantages are provided by the present invention of a training device for use in guiding and coordinating a user's body position when executing a golf swing like motion. The device comprises a first actuator for monitoring the movement of the upper torso of the user during the motion, and for applying a resistance force to the upper torso to guide the user in moving the upper torso in a desired manner; a second actuator for monitoring the movement of the wrists and arms, and for applying a resistance force to the wrists to guide the user in moving the wrists and arms in a desired manner; and a control unit connected to the first and second actuators for recording the movement monitored by the actuators and for operating the actuators to apply the resistance forces.

The foregoing and other features of the invention are hereinafter more fully described and particularly pointed out in the claims, the following description setting forth in detail certain illustrative embodiments of the invention, these being indicative, however, of but a few of the various ways in which the principles of the present invention may be employed.

30 **FIG. 15** is a front elevational view similar to **FIGS. 11-14** of the training device of **FIG. 1** being used by a user who is in the process of transitioning from the down swing to the follow through portion of a golf swing.

-13-

**FIG. 16** is a front elevational view similar to **FIGS. 11-15** of the training device of **FIG. 1** being used by a user who is in the process of executing the follow through portion of a golf swing.

## DETAILED DESCRIPTION OF PREFERRED EMBODIMENTS

### 5 Preferred Configuration of the Device

With reference to **FIG. 1**, the mechanical elements of the training device **10** of the present invention are essentially the same as that disclosed in U.S. Patent No. 6,371,863, issued to the present inventor, the disclosure of which is hereby incorporated by reference in its entirety. The device **10** includes a yoke **11**, a rotatable member **13**, and a guide assembly **19**. A user positions his or her upper torso in the yoke **11**, which includes an attachment point **12** for being positioned above and intermediate the user's shoulders. An end **14** of the rotatable member **13** is connected to the attachment point **12** of the yoke **11**. The rotatable member **13** has an axis of rotation **15** lying within a first plane **16** that is generally parallel to a target line **17**. The target line **17** is an imaginary line extending generally horizontally in the direction of an intended target from a predetermined point **18** at which the user would strike a golf ball with a golf club. The guide assembly **19** maintains the orientation of the rotatable member **13** as the user executes a golf swing relative to the target line **17**. The orientation of the rotatable member **13** is maintained by the guide assembly **19** as it simultaneously rotates and moves laterally generally parallel to the target line and vertically. Preferably, the guide assembly **19** maintains the orientation of the rotatable member **13** such that a first angle **20** between the first plane **16** and a horizontal plane **21** that contains the target line **17**, and a second angle **22** between the axis of rotation **15** of the rotatable member **13** and a line of intersection **23** between the first plane **16** and the horizontal plane **21**, both remain constant while the rotatable member **13** simultaneously rotates and moves laterally generally parallel to the target line **17** away from the target and toward the horizontal

-14-

plane **21** as the user executes a back swing and counter-rotates and moves laterally generally parallel to the target line **17** toward the target and away from the horizontal plane **21** as the user executes a down swing and follow through. The various elements comprising the invention are discussed in greater detail below.

With reference to **FIG. 2**, in a preferred embodiment, the yoke **11** comprises a front portion **24** that is intended to be disposed generally adjacent to the user's chest, a back portion **25** that is intended to be disposed generally adjacent to the user's back, and a connecting portion **26** connecting the front portion **24** and the back portion **25** and extending to an attachment point **12** that is intended to be positioned above and intermediate the user's shoulders. The yoke **11** preferably includes a linkage **27** for adjusting the distance between the front portion **24** and the back portion **25** of the yoke **11**. The front portion **24** of the yoke **11** also preferably includes one or more connection points **28** for pivotally connecting an optional extensible rod **57** and club holder **61** assembly (shown in **FIG. 8** and **FIG. 9**) to the yoke **11** proximal to the user's sternum.

The yoke **11** is used to guide the user's upper torso through the correct rotational, lateral, and vertical movements during a golf swing. Accordingly, it is preferably constructed of a substantially rigid material, such as, for example, metal, wood, plastic, or fiberglass, that can retain its shape and resist deformation when the user exerts pressure against the yoke **11** while attempting to move in an improper manner during a golf swing. It will be appreciated that the precise configuration of the yoke **11** is not per se critical and that any configuration that is capable of comfortably engaging the upper torso of the user and guiding and coordinating the user's movements during a golf swing could be used. For example, in an alternative embodiment the yoke **11** could comprise a fabric vest to be worn by a user that has a substantially rigid extension piece stitched into the back. In such an alternative embodiment, the rigid extension piece would include an attachment point **12** located above and intermediate the user's shoulders.

-15-

With reference to **FIG. 3** and **FIG. 4**, the guide assembly **19** comprises: a shaft **29**, a camming surface **33** and a generally C-shaped housing **34**. The shaft **29** is journaled for rotation on a substantially horizontal axis and has a first bevel gear **30** fixedly attached at one end and a cam follower **31** attached at the other end. The first bevel gear **30** meshes with a second bevel gear **32** that is attached to the rotatable member **13**. The axis of the second bevel gear **32** is the same as the axis of rotation **15** of the rotatable member **13**. The camming surface **33** is engaged by the cam follower **31**. The generally C-shaped housing **34** journals the shaft **29** and the rotatable member **13** in a fixed orientation relative to each other. The guide assembly **19** causes the rotatable member **13** to simultaneously rotate and move laterally generally parallel to the target line **17** and also toward or away from the horizontal plane **21** as the cam follower **31** rolls along in contact with the camming surface **33**.

Preferably, the camming surface **33** causes the rotatable member **13** to move laterally approximately 4.0 inches (10 cm) generally parallel to the target line **17** in a direction away from the target and approximately 0.75 inches (1.9 cm) toward the horizontal plane **21** while the rotatable member **13** rotates up to about 90° on the axis of rotation **15** as the user executes a back swing. The camming surface **33** also preferably causes the rotatable member **13** to move laterally approximately 8.0 inches (20 cm) in the opposite direction generally parallel to the target line **17** and approximately 2.5 inches (6.3 cm) away from the horizontal plane **21** while the rotatable member **13** counter-rotates up to about 180° on the axis of rotation **15** as the user executes a down swing and follow through. It will be appreciated that by changing the shape and/or length of the camming surface **33**, changes can be made in the amount of lateral and vertical movement permitted during the golf swing. Preferably, the camming surface **33** has a generally smooth arcuate profile that is relatively flat (i.e., generally parallel to the horizontal plane **21**) where the cam follower **31** contacts the camming surface **33** during that portion of the golf swing where user would strike the golf ball with the golf club (i.e., the bottom of the down swing).

-16-

The rotatable member 13 is connected to a rotational actuator 71 that is mounted atop the guide assembly 19. The rotational actuator 71 monitors and/or drives the rotation of the member 13. In the monitoring mode, the actuator 71 uses its rotational sensor to sense the rotation of the member 13 and to provide a digital output in accordance with this rotation. In the drive mode, the rotational actuator drives the rotation of the rotational member 13 in either direction. As the rotational member 13 is rotated by the actuator 71, it causes the yoke 11 to rotate and move horizontally through the golf swing motion. The actuator 71 may comprise a suitable servo motor that is capable providing sufficient torque to drive the rotational member 13 and that includes a rotary sensor to sense the angular position and/or number of revolutions of the rotational member 13 and provide a digital signal in response to each incremental angular change and/or revolution. Preferably, the torque applied by the servo motor is variable, so that a small urging force can be applied to the person using the device 10 which the user can override with his or her own motion, and so that the user is not injured when using the device 10. Suitable servo motors are commercially available and need not be described in further detail.

FIG. 5 provides a more detailed view of the guide assembly 19. The guide assembly 19 further comprises a pair of first rails 35, a carriage assembly 36, a plate 39, a pair of opposing rail mounts 42a, 42b, a drum 43, and a cable 44. The pair of first rails 35 is mounted within the generally C-shaped housing 34 so as to extend generally parallel to the axis of rotation 15 of the rotatable member 13. The carriage assembly 36 includes a pair of first bushings 37 that guide and slidably support the pair of first rails 35. The carriage assembly 36 rides on and is supported by a pair of second rails 38 that extend generally perpendicular to the axis of rotation 15 of the rotatable member 13 and that extend generally parallel to the target line 17. Although a pair of first rails 35 and a pair of second rails 38 are shown, a single first rail 35 and/or a single second rail 38 may be used in each instance. The plate 39 has a front surface 40 and a rear surface 41. The front surface 40 of the plate 39 includes a camming surface 33 for engagement by the cam follower 31.

-17-

The camming surface **33** thus defines and limits the movement of the rotatable member **13** laterally generally parallel to the target line **17** and with respect to the horizontal plane **21**. The pair of opposing rail mounts **42a**, **42b**, project from the front surface **40** of the plate **39**. The pair of second rails **38**  
5 are mounted between the pair of opposing rail mounts **42a**, **42b** in a fixed relationship generally parallel to the front surface **40** of the plate **39**. The drum **43** is mounted concentrically on the shaft **29**. The cable **44** extends between the pair of opposing rail mounts **42a**, **42b** and makes frictional contact with the drum **43**. The friction between the cable **44** and drum **43**  
10 causes the shaft **29** to rotate in relation to the movement of the cam follower **31** along the camming surface **33**.

Springs **45** are placed around the pair of first rails **35** between the housing **34** and the carriage assembly **36** to provide for smooth operation of the guide assembly **19**. Preferably, the springs **45** provide sufficient  
15 resistance to urge the yoke **11** to seek the address position when the training device is not in use, but also have sufficient compressibility to permit the rotatable member **13** to easily move toward and away from the horizontal plane **21** during the golf swing. When the yoke **11** is properly balanced using springs **45** in this manner, the user does not feel the weight of the yoke **11** or  
20 any appreciable resistance when executing a golf swing using the training device according to the present invention.

Another more preferred embodiment of the guide assembly **19'** is depicted in FIG. 6. In this embodiment, the rotatable member **13'** comprises an upper section **46** and a lower section **47** that are connected to each other,  
25 such as by a U-joint **48**. The axis of rotation **15'** of the lower section **47** of the rotatable member **13'** can be adjusted to suit the spine and tilt angle of the user and then fixed prior to use while at the same time keeping the axis of rotation of the upper section **46** generally perpendicular to the horizontal plane **21**. Preferably, the second bevel gear **32** is axially disposed with the upper  
30 section **46** of the rotatable member **13'**.

In the guide assembly **19'** of FIG. 6, the vertical movement of the rotatable member **13'** relative to the horizontal plane **21** during the golf swing

-18-

is determined by the preferably vertical orientation of the longitudinal axis of the pair of first rails 35, and not by the axis of rotation 15' of the lower section 47 of the rotatable member 13', which may deviate from vertical (such as when the first angle 20 and/or the second angle 22 are other than 90°). This configuration of the guide assembly 19' is presently more preferred because the upward and downward movement of the user relative to the horizontal plane 21 during the golf swing can be maintained in a vertical plane irrespective of the orientation of the axis of rotation 15' of the lower section 47 of the rotatable member 13'. In contrast, when the guide assembly 19 is configured as shown in FIG. 5, the upward and downward movement of the user relative to the horizontal plane 21 deviates from vertical as defined by the first angle 20 and second angle 22.

It will be appreciated that the training device 10 according to the present invention can be configured for use by right-handed and left-handed golfers simply by reversing the movements defined by the camming surface 33. Preferably, the guide assembly 19 is constructed from a rigid and durable material such as aluminum, steel, or plastic. It will be appreciated that there are a multitude of possible configurations for the guide assembly 19 that can accomplish the intended function of guiding and coordinating the movement of the rotatable member 13 as it simultaneously rotates and moves laterally and vertically when a user executes a golf swing.

The configuration of the drum 43 and cable 44 system used in the guide assemblies 19 and 19' illustrated in FIG. 5 and FIG. 6 is shown in greater detail in FIG. 7. One end of the cable 44 is attached to one of the opposing rail mounts 42a and extends laterally generally parallel to the front surface 40 of the plate 39 and bends around a first bearing 49 that is mounted on the carriage assembly 36 on the opposite side of the shaft 29 from the other rail mount 42b. The cable 44 then extends to and wraps clockwise completely around the drum 43 and then extends to and bends around a second bearing 50 that is mounted on the carriage assembly 36 on the opposite side of the shaft 29 as the first bearing 49. The cable 44 then extends from the second bearing 50 and is attached to the other rail mount

-19-

**42b.** As noted above, the friction between the cable **44** and drum **43** causes the shaft **29** to rotate in relation to the movement of the cam follower **31** along the camming surface **33**.

The diameter of the drum **43** determines the degree of rotation of the shaft **29** in relation to the movement of the cam follower **31** along the camming surface **33**. A larger drum **43** will not rotate as many degrees as a smaller drum **43** in relation to the same distance traversed by the cam follower **31** along the camming surface **33**. Preferably, the diameter of the drum **43** used in the device will cause the shaft **29** to rotate 90° during the user's back swing and 180° in the opposite direction as the user executes a down swing and follow through. It will be appreciated that the drum **43** can have an eccentric shape so as to cause the rotatable member **13** to rotate more or less during the back swing than during the follow through. It will be appreciated that belts or chains can easily be substituted for the cable **44**.

Although a cable **44** and drum **43** system as shown is preferred, it will be appreciated that there are a number of alternative embodiments that could equivalently accomplish the function of the cable **44** and drum **43** system within the scope of the present invention. For example, a rack and pinion arrangement could be used in which the camming surface **33** could be provided with a number of teeth that mesh with teeth in the cam follower **31** causing the shaft **29** to rotate. Alternatively, the cam follower **31** could be made of a material such as rubber that could frictionally engage the camming surface **33** and cause the shaft **29** to rotate. It will be appreciated that the mechanism that causes the shaft **29** to rotate is not per se critical to the invention, and that any method of coordinating the rotation of the shaft **29** relative to the movement of the cam follower **31** against the camming surface **33** would be suitable.

With reference to **FIG. 1**, in a preferred embodiment, the training device **10** according to the present invention further comprises a base **51** and at least one upright **52** connected to and extending from the base **51**. The upright **52** is connected to the rear surface **41** of the plate **39** to support the guide assembly **19** in the appropriate orientation relative to the user. In an

-20-

alternative embodiment, the guide assembly 19 could be supported by being mounted to a wall, by being hung from a ceiling or other overhead structure, or by being attached to some other support structure. Upright 52 has a generally horizontally extending arm 52a. The guide assembly 19 is mounted  
5 on the end of the arm 52a by attachment of the rear surface of the plate 39. The height of the arm 52a above the base 51 is preferably adjustable by means located at the junction of the upright 52 and the arm 52a.

In the preferred embodiment, the upright 52 permits the first angle 20, the second angle 22, and the distance between the rotatable member 13 and  
10 the horizontal plane 21 to be adjusted before the user executes a golf swing. Alternatively, the guide assembly 19 could be configured such that the first angle 20, the second angle 22, and the distance between the rotatable member 13 and the horizontal plane 21 could be adjusted before the user executes a golf swing. It will be appreciated by those having skill in the art  
15 that such adjustability can easily be built into the housing 34 of the guide assembly 19.

With reference to FIG. 1, the training device 10 according to the present invention can also optionally include a brace 53 connected to and extending from the base 51. The brace 53 makes contact with and limits the  
20 movement of at least one of the user's legs as the user executes a golf swing. In a preferred embodiment, the lateral position of the brace 53 can be adjusted by inserting brace pins 54 into one of a line of corresponding brace pin receiving holes 55 provided laterally in the base 51. Additionally, the height and orientation of the brace 53 can be adjusted using a pivoting clamp  
25 assembly 56. It will be appreciated that the brace 53 need not be connected to the base 51, but could be a free standing structure independent of the base 51.

With reference to FIG. 8, the training device 10 according to the present invention also optionally comprises an extensible rod 57, a club  
30 holder 61, and a hinge 62. The extensible rod 57 has a longitudinal axis 58, a first end 59, and a second end 60. The first end 59 of the extensible rod 57 is pivotally connected to a connection point 28 the front portion 24 of the yoke

-21-

11 that is intended to be proximal to the user's sternum. The club holder 61 supports, cradles or attaches to the grip end of the golf club shaft. The hinge 62 connects the club holder 61 to the second end 60 of the extensible rod 57. The hinge 62 has a pivot axis 63 that is disposed generally perpendicular to the longitudinal axis 58 of the extensible rod 57. Preferably, the pivot axis 63 is disposed such that it is near the center line of a right-handed user's left wrist (reversed for a left-handed user) when the training device 10 is being used. This location of the pivot axis 63 ensures that the user's wrist maintained is in the correct position throughout the golf swing. The club holder 61 is preferably an elongated semicylindrical trough into which the grip of the golf club is placed. When the user grips the club with the club holder around the bottom of the grip, the club is held securely in the training device. Alternatively, if the training device is used without a golf club, the user can simply grip the club holder as he or she would ordinarily grip a golf club.

It will be appreciated that the preferred configuration of the club holder 61 described above is but one possible configuration which would be suitable for use in the invention and that other configurations for the club holder 61 can be used. For example, the coupler configuration disclosed in the aforementioned U.S. Pat. No. 6,371,863 could be employed. Alternatively, the club holder 61 could comprise a socket formed of a resilient material that slides over and frictionally engages the grip end of a golf club. The club holder 61 could also comprise a rigid collar sized to easily slide over the grip end of a golf club and be attachable thereto using threaded fasteners which press against the grip end of the golf club as they are tightened. Essentially, any configuration which includes means for stabilizing the holder 61 to the grip end of a golf club and a source for permitting the holder 61 to be connected to the second end 60 of the extensible rod 57 by a hinge 62 would be suitable.

A second actuator 72 is mounted on the front portion 24 of the yoke 11, and is connected by a rotatable shaft 73 and gears 74 to a longitudinally-moving rod 75. The actuator 72 controls or monitors the vertical elevation of the golf club relative to the arc through which the golfer is swinging. As the

-22-

golfer begins the back swing, the club is elevated as the golfer turns to the back swing position. Then the club is brought downwardly to hit the ball, and it is brought upwardly again after hitting the ball in the follow through. The actuator **72** monitors or controls this vertical movement of the club, through  
5 the associated pivoting of the club holder **61** relative to the yoke **11**. The actuator **72** may be of the same or similar type as the actuator **71**, i.e., a servo motor with an angular position sensor and a variable drive. The actuator **72** has a rotatable output shaft that is connected by gears **74** to the rod **75**, which is connected to the club holder **61**. The gears **74** translate the rotational  
10 movement of the shaft **73** to linear movement by the rod **75**. Similarly, the gears **74** translate linear movement by the rod **75** into rotary motion by the shaft **73**. The rod **75** is connected at its distal end to the club holder **61**, so that as the club holder pivots as the user moves the club head up and down, the rod **75** moves longitudinally. This motion is then translated by the gears  
15 **74** to rotational motion applied by the shaft **73** to the actuator **72**.

As shown in **FIG. 9**, the actuators **71** and **72** are connected by suitable connecting lines or cables to a control unit **81**. The control unit **81** may be located anywhere relative to the device **10**, but it is preferably positioned directly in front of the person who is using the device.

20 The control unit **81** is shown in greater detail in **FIG. 10**. The control unit **81** includes a mode switch **82** to set the control unit to either the "learn" mode or the "teach" mode. In the "learn" mode, the actuators **71** and **72** monitor the change in location of the yoke **11** and the grip holder **61**, and the history of these locations over a short period of time, e.g., 5 seconds, is  
25 recorded by the control unit **81**. In the "teach" mode, the control unit sends signals to the actuators **71** and **72** so that the actuators drive or power the movement of the yoke **11** and the grip holder **61**, to force the user to perform the desired motion for a golf swing.

The control unit **81** also has a start button **83**, which initiates either the  
30 recording of the golf swing in the "learn" mode, or the performance of the golf swing in the "teach" mode. If the desired the start button **83** can be positioned at a location remote from the housing containing the control unit **81**, so that

-23-

the user can actuate the start button while standing in the device **10**. A remote start button **83** can be connected to the housing of the control unit **81** by an appropriate wire or cable or by suitable remote control communications, such as RF or infrared, used in the remote control of home electronic devices, garage door openers and the like.

Monitoring lights **84-87** are also provided on the control unit **81** for use of the control unit in the "learn" mode. The monitoring lights **84** and **85** provide an indication of the position of the yoke **11** as monitored by the actuator **71**. The monitoring lights **86** and **87** provide an indication of the position of the grip holder **61** as monitored by the actuator **72**. The lights **84** and **86** indicate to the user that the shoulders and the club, respectively, are in the proper position to begin the swing. These lights are illuminated only if the actuators **71** and **72** sense that the user's initial position is approximately the same as the golf swing that the user is emulating. The positions need not be exactly the same, but need be the same within a predetermined tolerance. The lights **84** and **86** indicate to the user whether the rotation of the swing and the lift of the club, respectively, are outside a predetermined tolerance of the desired swing that the user is attempting to emulate while the user is performing the golf swing motion. The control unit compares the actual positions monitored by the actuators **71** and **72** and compares them with the desired swing. If the actual position is outside the tolerance, the light **85** or **87** is illuminated, depending upon which actuator position is outside the desired range. Preferably, the lights **84** and **86** are green, and the lights **85** and **87** are red, as indicated by the letters G and R in FIG. 10, but any suitable colors or differentiating indicators can be applied to the lights, so long as the user is able to distinguish them and quickly comprehend what the lights indicate. If desired the lights **84** and **86** can be replaced or supplemented with an audible device which produces an predetermined sound or audible tone to indicate whether the rotation of the swing or the lift of the club is outside a predetermined tolerance of the desired swing that the user is attempting to emulate.

The control unit **81** also comprises a display screen **88** that provides a visual indication to the user of the golf swing being performed. The display screen **88** provides a read-out preferably comprising a time plot of each of the two swing parameters being monitored. One curve **89** can represent the change in the yoke position over time and the other curve **90** can represent the change in the grip holder **61** over time. The curves **89** and **90** can be made different colors on the display screen **88** or otherwise differentiated so that they can be easily distinguished. If the user is emulating a golf swing with the control unit **81** in the "teach" mode, the desired golf swing can be presented on the display screen **88** along with the actual swing being performed by the user, so that both swings can be compared.

The control unit **81** can suitably comprise a conventional personal computer (PC) programmed to perform the desired functions. A PC would provide the display screen **88**. Suitable control switches, buttons and lights can be connected to the PC to provide the switch **82**, the button **83**, and the lights **84-87**. PC-controlled drivers for the servo motors which comprise the actuators **71** and **72** are commercially available and can be suitably employed to connect the actuators to the PC which functions as the control unit. These items are readily available commercially and need not be described in detail.

## **20 Preferred Method of Using the Device**

When the training device **10** according to the present invention is used to train a user to perform a golf swing, it can be used with or without a golf club, with or without a golf ball, with or without the optional extensible rod **57** and club holder **61** assembly, and with or without the optional brace **53**. Even when the training device is used without a golf club, a golf ball, the optional extensible rod **57** and club holder **61** assembly, and the optional brace **53**, a user nevertheless obtains substantial benefit simply by using the device to practice the rotational, lateral, and vertical movements involved in executing a proper golf swing. The training device **10** according to the present invention guides and coordinates the user's body position and lateral, vertical and

-25-

rotational movement according to predetermined input so that after executing several golf swings using the device, a user's muscles become accustomed to making the movements of a proper golf swing.

To use the training device **10** according to the present invention to train  
5 a user to perform a golf swing without a golf club, golf ball, the optional extensible rod **57** and club holder **61** assembly, and the optional brace **53**, a user first comfortably positions his or her upper torso in the yoke **11**. In a preferred embodiment, the yoke **11** includes a front portion **24** that is intended to be disposed generally adjacent to the user's chest, a back portion **25** that is  
10 intended to be disposed generally adjacent the user's back, and a connecting portion **26** connecting the front portion **24** and the back portion **25** and extending to an attachment point **12** that is intended to be positioned above and intermediate the user's shoulders. With his or her upper torso positioned in and engaged in the yoke **11**, the user takes a comfortable stance a  
15 distance away from and facing a predetermined point **18** where a golf ball would be placed. The user's feet should preferably be placed generally parallel to the target line **17** and astride an imaginary horizontal line perpendicular to the target line **17** that passes through the predetermined point **18** on which a golf ball would be placed. Although the position of the  
20 user's arms and hands is not critical, preferably the user's arms are extended away from his or her body in the direction of the predetermined point **18** where the golf ball would be placed, with the user's hands lightly clasped together as if the user were holding a golf club. The user is now in the address position.

25 The switch **82** of the control unit **81** is now placed in the "learn" position, so that the control unit will record the rotational action of the yoke **11** and the vertical angle of the club holder **61**. The start button **83** on the control unit **81** is then actuated, and the control unit begins to record the motion of the user through the rotation of the actuators **71** and **72**. The user begins the golf  
30 swing by rotating his or her hips and upper torso away from the intended target while simultaneously moving his or her arms away from the predetermined point **18** where the golf ball would be placed. This first part of

-26-

the golf swing is called the back swing. During the back swing portion of the golf swing, the training device **10** according to the present invention guides and coordinates the user's body position and rotational, lateral, and vertical movement. The yoke **11** guides the user's upper torso through the proper positions during the golf swing, allowing the user's shoulders to rotate preferably up to about 90° away from the target from the address position while simultaneously allowing the axis on which the user's upper torso is rotating to move laterally generally parallel to the target line **17** away from the target a few inches and toward the horizontal plane **21**. The extent of this movement and the time it takes to complete the movement is recorded by the control unit **81** through the input received from the actuator **71**. The yoke **11** also prevents the user from moving his or her upper torso into an incorrect position during the back swing. At the same time, the user lifts the golf club into the air by raising the angle at which he or she holds the shaft of the golf club. As the golf club shaft is raised (or if no club is used, the club holder is raised in the user's hands), the other actuator **72** monitors this movement and sends the appropriate signal to the control unit **81** where it is recorded.

At the top of the back swing, the user's shoulders have preferably rotated away from the target to a position that is about 90° from the address position. It will be appreciated that some users of the training device **10** according to the present invention will not have the flexibility to rotate their shoulders 90° from the address position. However, because the training device **10** according to the present invention coordinates and guides the user's body position and lateral, vertical, and rotational movements during the golf swing, at whatever degree of rotation the user is able to accomplish, the device will maintain the user's body in the proper relative position. The actuator **71** will also record the final position of the user, so that the extent to which the user does not extend the back swing can be analyzed. It will be appreciated that through use of the device, some users will develop the flexibility needed to execute a full 90° rotation, which is sometimes called a turn. The device promotes a more complete body turn, rather than a twisting of the body, thereby reducing back tension.

-27-

From the top of the back swing, the user executes the down swing portion of the golf swing. The movements involved in the down swing are, in essence, the reverse of the movements involved in the back swing. During the down swing, the user's shoulders counter-rotate back toward the address position in the direction of the intended target. The training device 10 according to the present invention guides and coordinates the user's body position and lateral, vertical, and rotational movement during the down swing. The yoke 11 prevents the user's upper torso from moving in an incorrect manner, and causes the user to execute the movements involved in the down swing in a coordinated manner. During the down swing, the user's upper torso rotates back toward the address position on an axis of rotation 15 that simultaneously moves laterally in the direction of the target generally parallel to the target line 17 and away from the horizontal plane 21. At the same time, the user brings the head of the golf club down so that it will be in position to hit the ball. The speed and coordination of these movements is monitored by the actuators 71 and 72, and recorded by the control unit 81.

At the bottom of the down swing, the user has essentially returned to the address position. At that point, the user's movements transition into the follow through portion of the golf swing. During the follow through portion of the golf swing, the user's shoulders continue to rotate in the direction of the intended target preferably up to about 180° from the position they were at the top of the back swing and up to about 90° from the address position. Again, some users will not initially possess the flexibility needed to execute a full turn, but such flexibility can be developed through repeated use of the device. Also the extent of the follow through is recorded so that the user can see the extent to which the follow through has been completed. During the follow through, the user's upper torso continues to rotate toward the target on an axis of rotation 15 that simultaneously moves laterally in the direction of the target generally parallel to the target line 17 and away from the horizontal plane 21.

After a desired golf swing has been performed and recorded by the device, the user can be positioned in the device at any time to repeat this

-28-

desired swing motion as many times as the user wishes. The user is positioned in the device and the switch 82 of the control unit 81 is placed in the "teach position." The user positions the shoulders and arms so that both indicator lights 84 and 86 are illuminated, indicating that the user is in the proper position to begin the swing. The start button 83 is actuated, and the actuators 71 and 72 drive or power the movement of the yoke 11 and the club holder 61 to force the user to perform the desired golf swing. The amount of resistance or force provided by the actuators 71 and 72 is programmable and is determined by the program executed by the control unit 81. It may be desirable in certain circumstances to provide light resistance to the user who needs only gentle urging to assume desired swing motion characteristics. In other circumstances, such as with a novice golfer, a more forceful action may be required, so that the user is required to execute the desired motion exactly.

Through repeated swings, the user's muscles will become accustomed to executing the golf swing as guided and coordinated by the training device 10 according to the present invention. Initially, the user will most likely bear pressure against the yoke 11 in an attempt to move his or her upper body in an improper manner. However, after taking several swings with his or her upper body positioned in the yoke 11, the user will become used to the movements involved in executing a proper golf swing. After using the device for a while, the user will be able to execute the golf swing without bearing any significant pressure against the yoke 11. Using the device, the user grooves these movements, meaning that the user's muscles acquire a "muscle memory" of the proper golf swing, which the user can then confidently repeat on the golf course when he or she is not using the device.

The training device 10 according to the present invention is useful for teaching novice golfers how to execute the movements involved in the golf swing. It is also useful for helping those persons who golf regularly to identify and correct swing flaws or faults that have been acquired and grooved into their golf swings over time. Because the device trains the user to execute the same movements in a coordinated manner, the device is also useful for helping golfers to quickly regain and restore their golf swings after periods of

-29-

inactivity. Furthermore, because the device holds the user's upper torso in the proper position during the golf swing, the device is useful for allowing the golfer to stop and hold various positions during a golf swing while receiving instruction from a trained golf teaching professional.

5           It is possible to have available and recorded within the control unit **81** a number of ideal golf swings, such as those executed by famous professional golfers. With the availability of such golf swing motions, the user can be positioned in the device, set the control unit to the "teach" mode, and experience the performance of a different golf swing and one which may have  
10       been highly successful for a famous golfer. While such recorded swings may not be the ideal for another golfer, they do allow the golfer to experience different golf swing motions that are successful for others and allow the golfer to experiment with changes in his or her golf swing.

          In a preferred method of use, a user uses the training device **10**  
15       according to the present invention while gripping and swinging one of the user's golf clubs that are used in actual play. To use the device in this manner, the user simply takes a comfortable grip on the grip end of a golf club and places the head of the golf club near the predetermined point **18** at which a golf ball would be placed on the side opposite the intended target. The user  
20       then executes the movements involved in executing the back swing, the down swing, and the follow through while his or her upper torso is positioned in and engaged by the yoke **11**.

          More preferably, the user also uses a golf ball while using the device. The user places the club head next to the golf ball, which has been placed in  
25       a predetermined position on the target line **17**, on the side opposite the intended target and then executes the movements involved in executing the back swing, the down swing, and the follow through while his or her upper torso is engaged in the yoke **11**. At the bottom of the down swing, the user will strike the golf ball with the golf club. After practicing the golf swing using  
30       the device, the golfer will be able to see, hear, and feel a golf club striking a golf ball as the user's body position and lateral, vertical, and rotational

-30-

movements are being guided and coordinated through a proper golf swing by the training device **10** according to the present invention.

The sense of touch is very important in the game of golf. It is sometimes difficult for a user to translate the feeling of a practice device to the feeling a user has while gripping the user's own playing clubs. The training device **10** according to the present invention is particularly useful because it allows the user to practice hitting golf balls while gripping his or her own playing clubs. Thus, by using the training device **10** according to the present invention, it is not necessary for the user to attempt to translate the feeling of a practice device to the feeling of the user's own playing clubs.

To use the training device **10** according to the present invention to practice a golf swing using the optional extensible rod **57** and club holder **61** assembly, a user places the club holder **61** around the grip end of a golf club in a manner so as to fix the pivot axis **63** of the hinge **62** generally perpendicular to the horizontal grooves in the face of the golf club. It will be appreciated that users who have mastered the basic golf swing may vary the fixed relationship between the pivot axis **63** of the hinge **62** and the horizontal grooves in the face of the golf club in order to practice special shots, such as fades or draws, where the rotation of the golf ball relative to the target line **17** is intentionally altered from perpendicular. In either event, the user takes a comfortable grip predominantly on the uncovered portion of the grip of the golf club. Because the profile of the club holder **61** is relatively slim, a portion of the golfer's grip may be on the club holder **61**. The user then assumes an address position with the head of the golf club placed on the side of the golf ball opposite the intended target.

**Figs. 11-16** are a series of front elevational views of a right-handed user **89** using the training device **10** according to present invention with the optional extensible rod **57** and club holder **61** attached to the grip end of a golf club **90** to execute a golf swing. In order to demonstrate the lateral and vertical movements involved in a golf swing conducted by a user **89** of the training device **10** according to the present invention, fixed vertical reference line **A-A** and fixed horizontal reference line **B-B** have been added to **Figs. 11-**

-31-

16 so that the relationship between such reference lines and the attachment point 12 between the yoke 11 and the end 14 of the rotatable member 13 can be observed as the user 89 executes a golf swing.

In FIG. 11, the user 89 is facing a golf ball 92 that at rest on a predetermined point 18 on the ground. The upper torso 91 of the user 89 is positioned in and engaged by the yoke 11. Note that in FIG. 11, the fixed vertical reference line A-A and the fixed horizontal reference line B-B intersect at the attachment point 12 between the yoke 11 and the end 14 of the rotatable member 13. The attachment point 12 is positioned above and intermediate the user's shoulders. The back portion 25 of the yoke 11 stays in contact with the user's back, and in so doing keeps the attachment point 12 in the same position relative to the user's shoulders throughout the swing. Preferably, the axis of rotation 15 passes through at least a portion of the user's spine.

While in the address position, the hinge 62 permits the user to raise and lower the golf club and thereby change the lie angle between the bottom of the club head and the ground to suit the user's stance. Once a comfortable stance has been obtained, the user begins the back swing by turning the shoulders and hips which rotates the golf club away from the golf ball initially along the target line 17. One of the common swing flaws encountered by golfers is that the back swing is initially executed by the golfer lifting the head of the golf club off the ground by using the arm muscles and/or by bending the joints of the wrist and/or elbow. The extensible rod 57 coupled with the hinge 62 prevent the user from initially executing the back swing by using the arm muscles and/or by bending the joints of the wrist and/or elbow. Instead, the user learns to execute a back swing that involves rotating the user's body while simultaneously moving the upper body laterally generally parallel to the target line 17 away from the target and toward the horizontal plane 21. For a right-handed user, brace 53 (not shown in FIG. 11) can optionally be used to restrain the user's right leg from making any lateral movement while simultaneously permitting rotational movement, thereby creating a post on

-32-

which the user's upper body and hips can rotate. For a left-handed user, the brace 53 is used to restrain the movement of the user's left leg.

As the user continues to execute the back swing and complete the turn away from the intended target, the extensible rod 57 attached to the yoke 11 operates to keep the user's arms moving together in the proper position relative to one another, and in relation to the user's upper body and, in particular, to the user's sternum. Another common swing flaw involves the bending of the elbows, particularly the left elbow for a right-handed golfer, which causes the golf club to get into an improper position. The extensible rod 57 keeps a right-handed user from bending the elbows in an improper manner and allows centrifugal force from the rotation to extend the user's left arm (a left-handed user's right arm would be extended). The extensible rod 57 also prevents the destruction of centripetal force, which is required to maximize club head speed created by the rotation and centrifugal force.

FIG. 12 shows the right-handed user 89 in the process of executing a back swing while using the training device 10 according to the present invention. The upper torso 91 of the user 89 has rotated away from the intended target as the user 89 and the golf club 90 has rotated away from the golf ball 92. Note that the attachment point 12 between the yoke 11 and the end 14 of the rotatable member 13 has moved laterally away from the intersection of the fixed vertical reference line A-A in a direction away from the target and that the attachment point 12 between the yoke 11 and the end 14 of the rotatable member 13 has also moved toward the horizontal plane 21 and thus is now below the fixed horizontal reference line B-B.

As the user approaches the top of the back swing, the hinge 62 between the extensible rod 57 and the club holder 61 allows the user to cock his or her wrists in the appropriate plane at the appropriate point in the swing. By encouraging a full body turn, at the top of the back swing the golf club will preferably be oriented such that the shaft of the golf club is generally parallel to the target line 17. The left elbow joint, for a right-handed user, will be higher than the right elbow joint at the top of the back-swing. This is the correct position that comes about as the training device 10 according to the

-33-

present invention guides and coordinates the user's body position and lateral, vertical, and rotational movement during the back swing.

**FIG. 13** shows a right-handed user **89** at the top of the back swing. At the top of the back swing, the shaft of the golf club **90** is preferably generally parallel to the target line **17**. At the top of the back swing, the shoulders of the user **89** have rotated to a position that is about 90° away from the position they were in at address in a direction away from the target. During the back swing, the attachment point **12** between the yoke **11** and the end **14** of the rotatable member **13** moves away from the intended target laterally generally parallel to the target line **17** and toward the horizontal plane **21**, as can be seen from its position to the right of and below the fixed vertical and horizontal reference lines **A-A** and **B-B**, respectively.

From the top of the back swing, the head of the golf club reverses direction and begins moving along a path that will eventually cause it to collide with the golf ball. This movement is generated primarily by the user's body, which has previously executed a turn in order to complete the back swing (preferably up to about 90° at the shoulders and up to about 45° at the hips or waist from the address position), turning back toward the ball. As the user's body rotates back toward the golf ball, gravity and centrifugal force cause the user's arms to move back toward the initial address position. The yoke **11** contacts the user's upper torso and guides and coordinates the user's body position and lateral, vertical, and rotational movement during the swing. Centrifugal force, which is generated by the rotation of the user's hips, upper body, and arms about the axis of rotation **15** causes the golf club head to accelerate on an arc called the swing path. The training device **10** according to the present invention keeps the swing path of the club head generally along the target line **17** when the club head is in contact with the golf ball.

**FIG. 14** shows a right-handed user **89** who is in the process of executing the down swing portion of a golf swing. The golf club **90** is accelerating toward the golf ball **92** as the user **89** rotates back toward the address position. Note that the attachment point **12** between the yoke **11** and the end **14** of the rotatable member **13** is moving generally parallel to the

-34-

target line 17 in the direction of the target and away from the horizontal plane 21 as the user 89 rotates his or her hips and upper torso 91 back toward the address position in the direction of the target.

The head of the golf club accelerates as the shaft of the golf club head  
5 moves from a position at the top of the back swing that generally parallels the target line 17 to a position at the bottom of the down swing where the shaft of the golf club is generally perpendicular to the target line 17. The training device 10 according to the present invention together with the optional extensible rod 57 and club holder 61 assembly insures that the face of the golf  
10 club is maintained in a relatively square position relative to the target line 17. Because the extensible rod 57 and hinge 62 only permit the golf club to be moved on the proper axis, the horizontal grooves in the face of the golf club will be kept generally square or perpendicular to the target line 17 while the face of the golf club head is in contact with the golf ball. Also, the device  
15 prevents the user from moving in such a manner as to destroy the centripetal force which is necessary in order to maximize the centrifugal force exerted at the head of the golf club.

FIG. 15 shows a right-handed user 89 transitioning from the down swing portion of the golf swing to the follow through portion of the golf swing.  
20 The attachment point 12 between the yoke 11 and the end 14 of the rotatable member 13 has returned to the point where it is bisected by the fixed vertical and horizontal reference lines A-A and B-B, respectively. At this point in the golf swing, the head of the golf club 90 collides with and begins to transfer energy to the golf ball 92.

25 As the user continues the swing rotation, the golf ball springs off the face of the club head and flies in the direction of the target. The user will instantaneously see, hear, and feel what a properly struck golf ball looks, sounds, and feels like. The user finishes the golf swing rotation in a rotational move called the follow-through. As with the back swing, the training device 10  
30 according to the present invention guides the user's arms in the proper position relative to the golf club, which teaches the user to execute a full turn toward the target.

-35-

**FIG. 16** shows the position of a right-handed user **89** during the process of executing the follow through portion of a golf swing. Note that the attachment point **12** between the yoke **11** and the end **14** of the rotatable member **13** is now to the left of and above the fixed vertical and horizontal reference lines **A-A** and **B-B**, respectively. The training device **10** according to the present invention has guided and coordinated the rotational, lateral, and vertical movements of the upper torso of the user **89** throughout the golf swing.

In a preferred embodiment, the extensible rod **57** includes an upper portion **64** that is free to rotate on the longitudinal axis **58** relative to the lower portion **65**. By permitting this rotation along the longitudinal axis **58**, the user can learn to rotate or roll his or her wrists and arms in conjunction with a proper turn as the club face strikes the golf ball during the golf swing. Once learned through kinesthesia (i.e., by feel or muscle memory through sensory perception), this technique allows the user to hit a golf ball farther and with greater force than a swing without a wrist roll. For those users who are just beginning to learn how to execute a golf swing or who are correcting a previously grooved swing flaw, a locking pin **88** can preferably be used to restrict rotation of the upper portion **64** of the extensible rod **57** relative to the lower portion **65** until a swing with proper mechanics is learned and grooved. Thus, the training device **10** of the present invention allows the user to isolate various aspects of the swing in order to address certain swing flaws during practice.

The training device **10** is intended to involve as many of the user's senses as possible. The training device **10** provides a visual reference for the user to see where his or her arms, body, and golf club should be during a properly executed golf swing. Additionally, the training device **10** involves the user's sense of touch, or kinesthesia, by allowing the user to feel the grips of his or her own actual playing golf clubs as well as the contact between the user's upper torso and the yoke **11**. Moreover, the user can feel and hear what a properly struck golf ball is supposed to feel and sound like. In a preferred embodiment, the hinge **62** also includes a spring-loaded detent

-36-

which provides an audible click when the hinge 62 pivots on its pivot axis 63 during the golf swing. If the golf swing is being executed properly, the click of the detent will be heard when the user is in the same position each time.

It will be appreciated that the training device 10 according to the present invention can be attached to any of the user's playing actual playing clubs. Thus, a user can practice a golf swing and hit golf balls as noted above with each and every playing club, from a driver to a sand wedge. The device can be used to practice full swings to pitch shots and chip shots. Furthermore, the device can also be used to practice the putting stroke.

To use the optional brace 53, the brace 53 is connected to the base 51 by inserting brace pins 54 in corresponding brace pin receiving holes 55. The brace 53 is then adjusted using the pivoting clamp assembly 56 so that it contacts an appropriate point on either of the user's legs or hips. Depending upon the type of instruction being given to the user at a given time, the brace 53 can contact any point on either of the user's legs from the lower shin up to the user's hips. The brace 53 is used primarily to give the user something to bear against as a reference point during the swing, which helps the user create a stable foundation upon which the dynamics of the full swing are based. The brace 53 can help the user isolate the user's lower body relative to the upper torso during the golf swing.

In some respects, learning to properly execute a golf swing is similar to learning to play a musical instrument such as the piano. In both instances, one must engage in substantial practice in order to properly execute the necessary physical movements to accomplish the intended goal. In the case of learning to play the piano, one must train one's fingers to strike the proper keys in the proper order to make music. In the case of learning to properly execute a golf swing, one must train one's entire body to move in the proper position at all times during the swing in order to properly strike the golf ball. The principle difference between the two acts involves the lack of objective "keys" or positions in a golf swing as compared to most musical instruments. The keys on a piano are visible and in a fixed location and thus can be readily found and used as a reference point by one learning to play the piano.

-37-

Moreover, when an improper key is struck, one can audibly detect the error and strive to correct it. In contrast, one learning to execute a golf swing has no objective positions, keys, or other reference points to consult. The user must find swing positions (i.e., the "keys") without any fixed visual, audible, or tactile guidance. Furthermore, it is sometimes difficult for a golfer to appreciate the difference between a properly struck golf ball and one which was not hit properly.

The training device **10** according to the present invention provides the user with an objective set of "keys" that a user can use to locate proper, repeatable, consistent positions in a golf swing. Moreover, after practicing and learning the "key" positions of a properly executed golf swing using the training device **10** according to the present invention, the user can use the device to practice and implement variations on a properly executed swing that can enhance and improve his or her golf game. Continuing with the piano analogy, the ability of the user to learn variations of the golf swing is similar to the pianist learning to strike the keys of a piano in various interpretive ways (e.g., long notes, crescendos, staccato notes, and other interpretive moves). The interpretive shots in golf, which are essential to achieving low scores, involve varying such things as swing tempo, softness of shots, grip pressure, the angle of the blade of the club relative to the swing path, and other minor adjustments. In all cases, however, it is essential that the user have a constant set of positions or "keys" to serve as a reference point for the swing.

A preferred training device **10** according to one preferred embodiment of the invention preferably allows the user to adjust the first angle **20** and second angle **22** prior to executing the swing. The adjustment can be made in the upright **52** that supports the guide assembly **19**, or it can be made in the guide assembly **19** itself. The adjustment of the first angle **20** and second angle **22** allows the user to adjust the degree to which the golfer bends at the waist forward toward the golf ball at the address position, which is called a spine angle, and also the degree to which the golfer bends at the waist either toward or away from the target, which is called the tilt angle.

-38-

Another feature of the invention involves the ability of a user to use the device to quickly recover a proper swing after a lay off from playing golf or other periods of inactivity. Since there are generally no objective keys in a golf swing to serve as a frame of reference, a golfer who does not swing a golf club for a few days will begin to lose the feeling or kinesthesia of correct swing positions. However, through use of the training device 10 of the present invention, the golfer can return from a lay off to reasonable performance levels after a comparatively short period of practice because the device will help the golfer recall the "keys" or positions and motions of a properly executed golf swing. Rapidly refreshing one's muscle memory and maintaining the muscle tone for a golf swing can heighten a golfer's enjoyment of the game of golf and raise the golfer's confidence on the golf course.

While the device of the present invention has particular advantages in the teaching and training of a golf swing motion, the device may be employed to teach or train other similar motions. The motions of rotating one's upper torso and lifting and lowering one's arms are also employed in walking. Teaching persons these motor skills is sometimes important in physical therapy rehabilitation. The user can be positioned within the device, and the device can be programmed to guide the user in the "teach" mode through the motions of the upper torso and arms that are less extreme than those used to execute a golf swing, but are similar to those performed in walking. Through repeated use of the device, a person undergoing physical rehabilitation can be re-taught important motor skills that may have been lost due to illness or injury. Other similar motor skill exercises can be programmed into the device and used with rehabilitation patients or in kinesitherapy.

Additional advantages and modifications will readily occur to those skilled in the art. Therefore, the invention in its broader aspects is not limited to the preferred embodiments and illustrative examples shown and described herein. Accordingly, various modifications may be made without departing from the spirit or scope of the general inventive concept as defined by the appended claims and their equivalents.
